Introduction

Conclusion

The yeasts associated with mawè fermentation were *Pichia kudriavzevii* (66 % of the total isolated yeasts) at Mawè is a West African cereal-based spontaneously fermented dough. The fermentation of mawe is all stages of the fermentation; *Kluyveromyces marxianus* (25 % of the total isolated yeasts) mostly from the intermediate stage till the end stage; Saccharomyces cerevisiae (5 % of the total isolated yeasts) mostly dominated by yeasts and lactic acid bacteria (LAB) (Hounhouigan et al., 1994). However, the diversity of yeasts and LAB involved in maize mawe fermentation constituted a minor part, together comprising 4% of the total isolated yeasts. have only been investigated in urban processing units.

Aim

To identify yeasts and LAB occurring during spontaneous fermentation of mawe in diverse urban and rural maize or sorghum mawè processing units in Benin.

identified only at the end stage, Ogataea polymorpha, Candida glabrata and Wickerhamomyces anomalus

The LAB associated with mawe fermentation were *Lactobacillus fermentum* (87 % of the total isolated LAB) at all stages of the fermentation; *Pediococcus acidilactici* (5 % of the total isolated LAB) mostly from the intermediate stage till the end stage, *Lactobacillus plantarum* (4 % of the total isolated LAB) identified at all stages, Weissella confusa (3 % of the total isolated LAB) mainly detected at the onset of the fermentation and **Pediococcus pentosaceus** (1% of the total isolated LAB).

Materials & Methods

Four kinds of mawe including commercial maize and sorghum mawè, home mawè and mawè for come were sampled at different fermentation times from **eight** production sites in urban and rural area in southern Benin, West Africa. Samples were produced following the flow diagram Fig.1 and picture 1 shows a mawe production site.

Isolated yeasts (n = 334) and LAB (n = 344) were grouped by (GTG)5-based repetitive PCR followed by **sequencing** of the 26S rRNA gene for yeasts and the 16S rRNA gene for LAB. *Kluyveromyces* spp. were unambiguously identified to species level by restriction

fragment length polymorphism (RFLP) of internal transcribed spacer region followed by sequencing.

Results & discussion

For the four kinds of mawe, yeast counts increased continuously from 0 to 36h (Fig. 2a). LAB counts increased between 0 and 24h and thereafter decreased (Fig. 2b). The average value of pH decreased over time to 4.1±0.30.

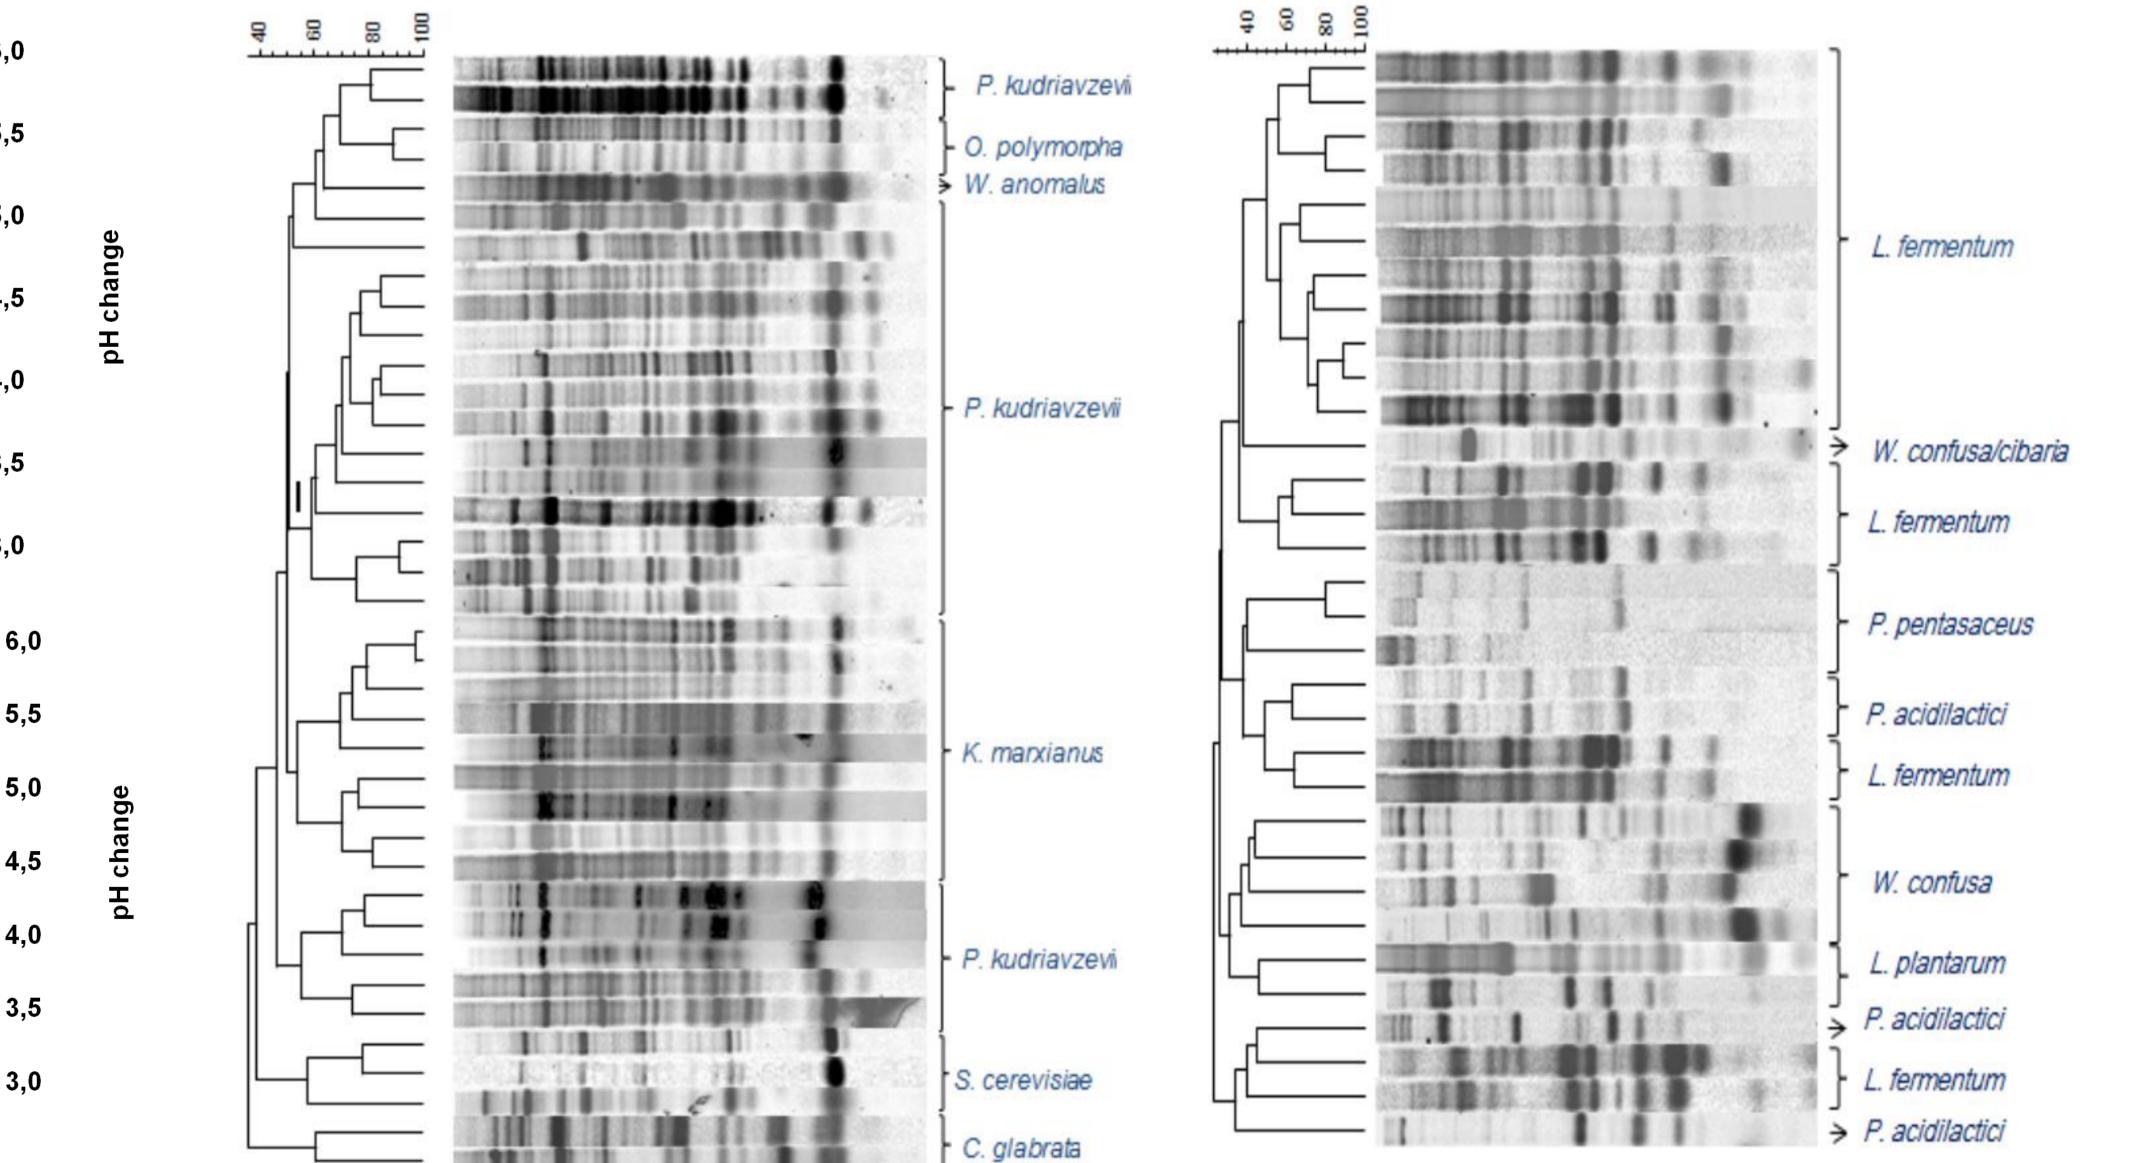

Final mawè

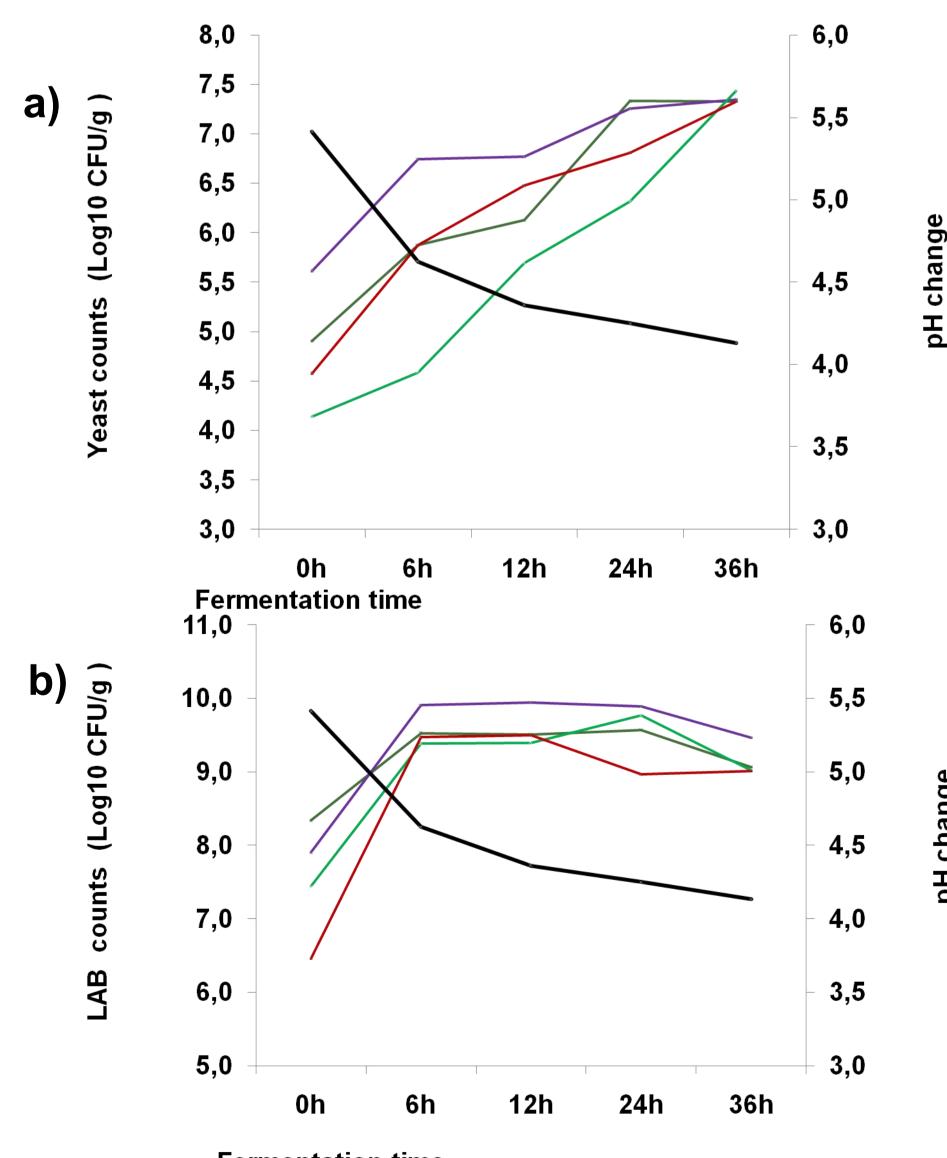

Fig. 1. Diagram flow of mawe production. The grits in not washed in home mawe processing. In come mawe processing, the cleaned maize is directly soaked in boiled water without grinding.

Picture 1. Mawè production site of St Michel market, Cotonou, Benin

The Rep-PCR profile and cluster analysis followed by gene sequencing showed that six different species of yeast (Fig. 3) and five different species of LAB (Fig. 4) are responsible of spontaneous fermentation of mawe.

The study confirm the findings of Hounhouigan et al. (1994) and Greppi et al. (2013). However **O. polymorpha** and *L. plantarum* have never been detected in mawe by the previous studies.

Fermentation time

- ---Commercial maize-based mawe
- --Home mawè
- ---Commercial sorghum-based mawe — Mawè for come
- --Average pH

Fig. 2. Microbial count and pH change during mawe fermentation

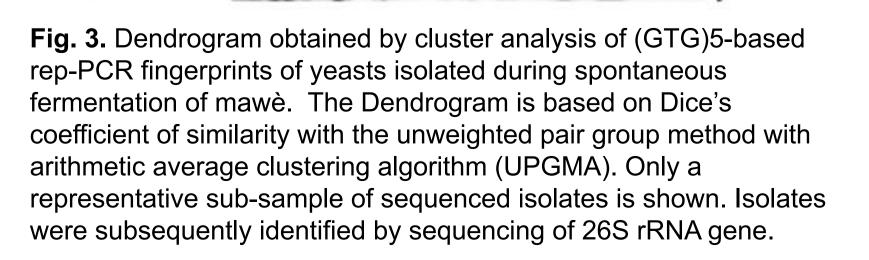

Fig. 4. Dendrogram obtained by cluster analysis of (GTG)5-based rep-PCR fingerprints of lactic acid bacteria isolated during spontaneous fermentation of mawe. The Dendrogram is based on Dice's coefficient of similarity with the unweighted pair group method with arithmetic average clustering algorithm (UPGMA). Only a representative_sub-sample of sequenced isolates is shown. Isolates were subsequently identified by sequencing of the 16S rRNA gene.
